

# Best Candidate Selection

BCS for  $\Xi_c(2970)^+$  from  $\Xi_c'^0\pi^+$

Taejin Moon

1 Nov, 2019

$$\Xi_c(2970) \rightarrow \Xi_c' \pi$$

# Best Candidate Selection

f) In the case of particles decaying to  $\Xi_c'$  only one  $\Xi_c'$  is allowed per event, to eliminate double-counting in events with noise photons

< from p.1 of bn1380 v2.0 >

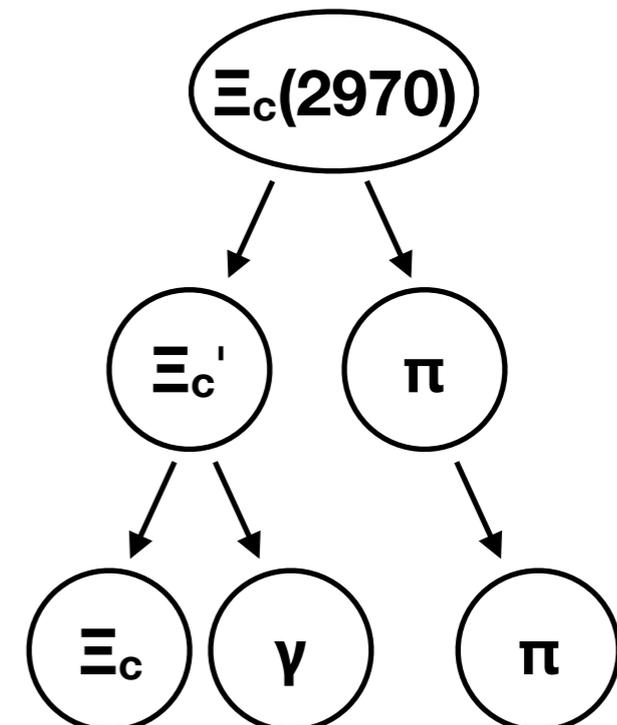

Because there is a good deal of background from noise “photons”, there is a possibility of falsely enhancing any peak in  $\Xi_c'/\pi$  distributions by having individual events enter the plots twice at similar total masses – once with the correct photon and once with a noise photon which is nearby. To reduce this effect, if there were multiple candidates in one event with the same transition pion but different  $\Xi_c'$  candidates, only the one with the  $\Xi_c'$  mass closest to the peak value was used. This reduced the final signal by around 10% but did not significantly change the mass and width values obtained.

< from p.24 of bn1380 v2.0 >

$\Xi_c(2645) \rightarrow \Xi_c$  decay. It is possible for background photons, particularly of low energy, to combine with the  $\Xi_c$  ground states to make  $\Xi_c'$  candidates. Once constrained to the  $\Xi_c'$  mass, several such candidates in one event can combine with a pion from a higher state to make multiple entries in this plot, all at similar total masses. To avoid this, we require that if there are multiple  $\Xi_c'$  candidates of this type in an event, only the one with an unconstrained mass closest to the  $\Xi_c'$  mass is considered. This reduces the overall population of the plot by around 15%.

J. Yelton et. al., PRD 94, 052011 (2016)

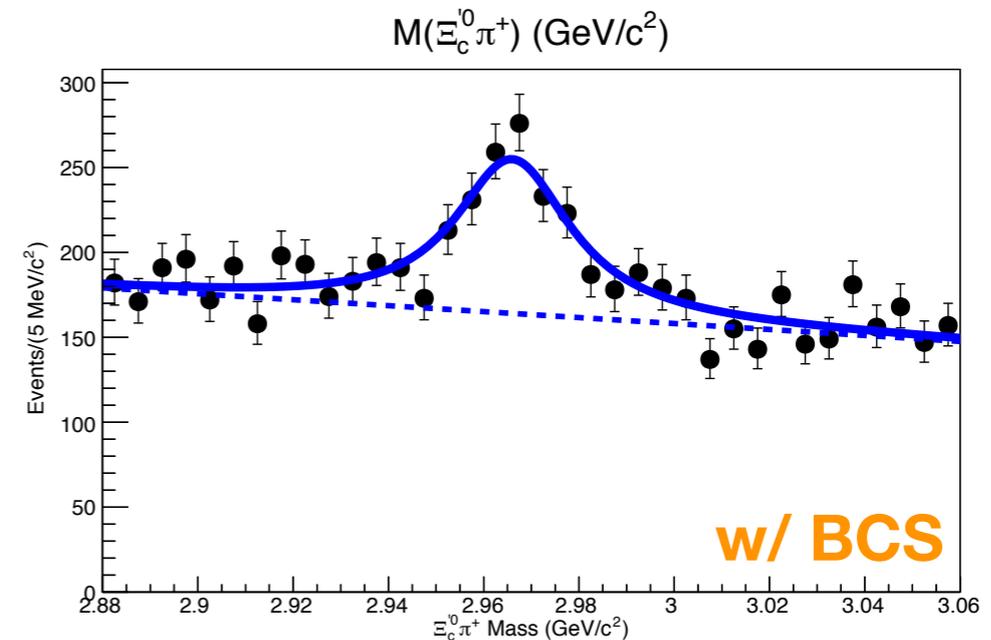

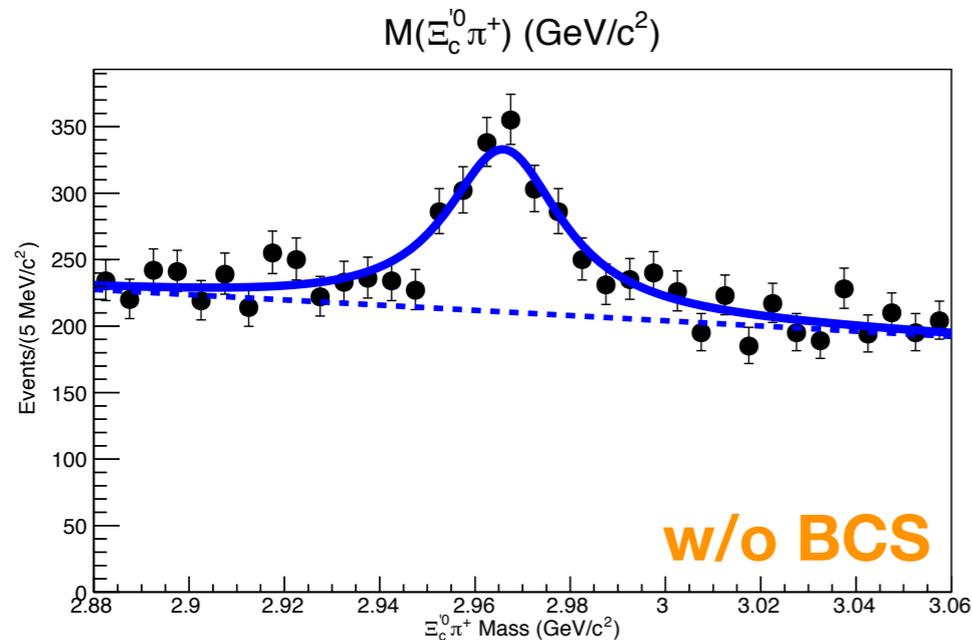

# Logic for BCS

	$\Xi_c'^1$	$\Xi_c'^2$	$\Xi_c'^3$
$\pi_1$	$\Xi_c(2970)$ cand 1	-	$\Xi_c(2970)$ cand 2
$\pi_2$	-	$\Xi_c(2970)$ cand 3	-
$\pi_3$	-	-	-

- In a event,
- Among  $\Xi_c(2970)$  candidates which come from  $\pi + \Xi_c'$ ,
  - For each pion,
    - If there is only one  $\Xi_c'$  partner, then flag==1 for  $\Xi_c(2970)$  candidate 3
    - If there are multiple partners,
      - let  $M(\Xi_c'^3)$  be closer to  $\Xi_c'$  mass than  $M(\Xi_c'^1)$
      - then flag==1 for  $\Xi_c(2970)$  candidate 2
      - then flag==0 for  $\Xi_c(2970)$  candidate 1

# Fitting Result

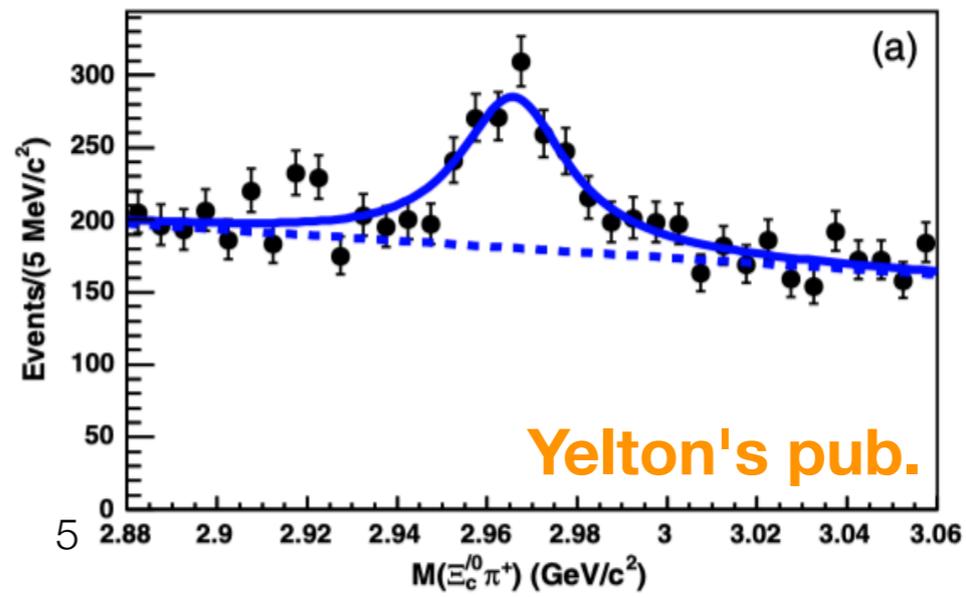

$\Xi_c(2970)^+ \rightarrow \Xi_c'^0 \pi^+ \rightarrow \Xi_c^0 \gamma \pi^+$   
 Angle integrated data.

	w/o BCS	w/ BCS	w/o $\rightarrow$ w/	cf. Yelton's

- Mass : 2966.0 MeV/c<sup>2</sup> (fixed)
- width: 28.1 MeV/c (fixed)

- Cut condition
  - $x_p > 0.7$
  - Window for  $M(\Xi_c')$ :  $\pm 8$  MeV
  - $E_\gamma > 100$  MeV
  - Proper charge of  $\pi$  selected .
  - $\chi^2$  vertex fitting for  $\Xi_c(2970) < 30$
  - Window for  $M(\Xi_c)$ :  $\pm 2\sigma$

# Summary

- By applying BCS, total entries decrease by 22.6% and yields decrease by 25.7%
- Statistics and peak shape are still different.
  - Total entries and yields w/ BCS is 90.7% and 87.6% of those in the Yelton's publication result, respectively.
  - BCS doesn't change peak shape so much.
